

Let's describe the damped oscillation of the end of the **first pendulum** (point D)  
 (you can brush-up your knowledge by searching the keyword "Lissajous"):

$$x_1 = A_1 \cdot \exp\left(\frac{-t}{t_{damping}}\right) \cdot \sin(2 \cdot \pi \cdot f_1 \cdot t)$$

$$y_1 = A_1 \cdot \exp\left(\frac{-t}{t_{damping}}\right) \cdot \sin(2 \cdot \pi \cdot f_1 \cdot t + \Delta\phi_1)$$

Initial amplitude (points to  $A_1$ )  
 Damping factor (points to  $t_{damping}$ )  
 Time (points to  $t$ )  
 Frequency (points to  $f_1$ )  
 Phase difference (points to  $\Delta\phi_1$ )  
 Damping coefficient (points to  $t_{damping}$ )  
 Overall Amplitude (bracket under  $A_1$ )

- The overall amplitude is not constant but will decrease exponentially in time
- The initial amplitude, damping coefficient, frequency, phase and phase difference are all adjustable
- A phase difference of  $0^\circ$  will result in a straight line oscillation, a  $90^\circ$  in a circle and in an ellipse for any angle in between

## Modeling rigid pendulum 2-D oscillations:

- Let's see some examples of how the trajectories might look like. Below there are the oscillation equations of the first pendulum

The diagram shows two equations for pendulum oscillations,  $x_1$  and  $y_1$ , with various parameters highlighted and labeled:

- $x_1 = A_1 \cdot \exp\left(\frac{-t}{t_{damping}}\right) \cdot \sin(2 \cdot \pi \cdot f_1 \cdot t)$
- $y_1 = A_1 \cdot \exp\left(\frac{-t}{t_{damping}}\right) \cdot \sin(2 \cdot \pi \cdot f_1 \cdot t + \Delta\varphi_1)$

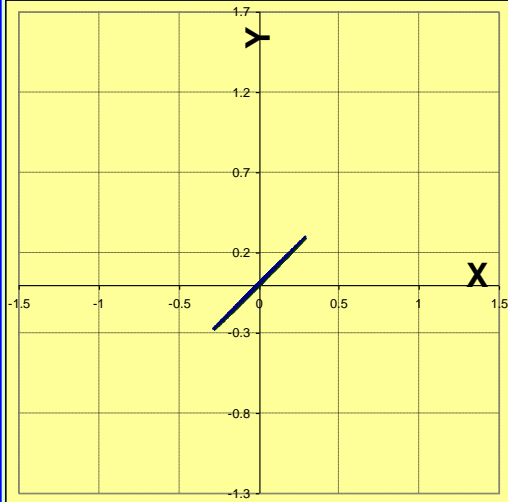

Annotations and labels:

- Initial amplitude:** Points to  $A_1$  in the first equation.
- Damping factor:** Points to the  $t_{damping}$  term in the denominator of the exponential function in the first equation.
- Time:** Points to  $t$  in the sine function of the first equation.
- Damping coefficient:** Points to the  $t_{damping}$  term in the denominator of the exponential function in the second equation.
- Frequency:** Points to  $f_1$  in the sine function of the second equation.
- Overall Amplitude:** A bracket under  $A_1$  in the second equation.
- $\Delta\varphi_1$ :** Points to the phase shift term in the second equation.

- Insert a worksheet named "Pendulum\_Equations" and create a table of data: X(t) and Y(t). After that, we save several parametric plots of data to see the effect of the oscillation parameters on the shape of the pendulum trajectories.

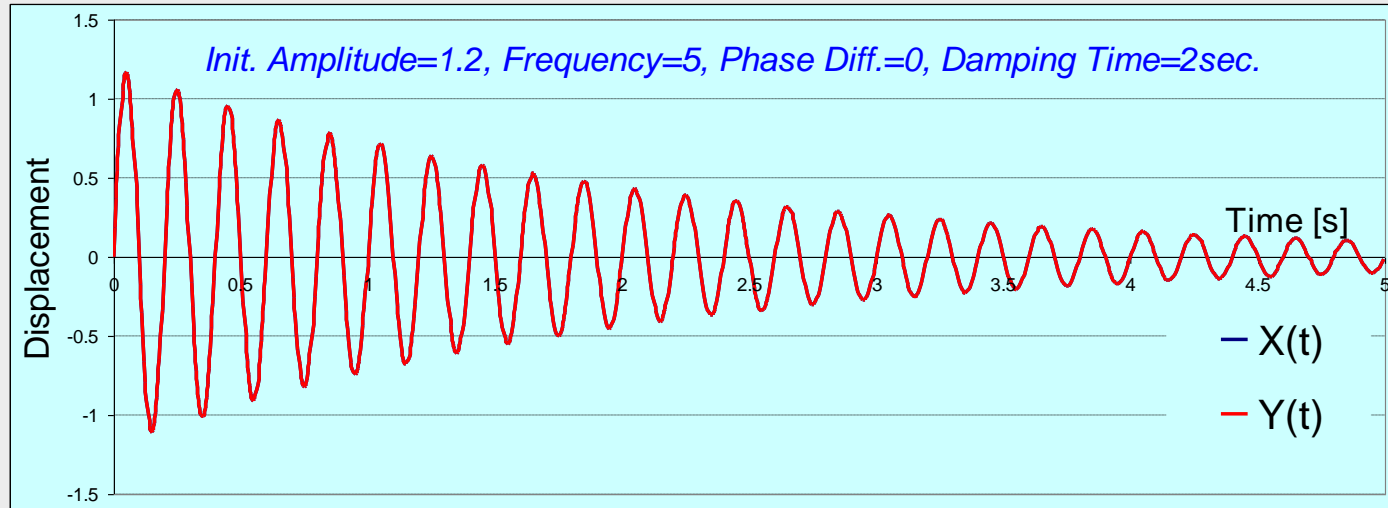

## Pendulum Parameter Effects:

- Let's see several examples of effects of pendulum parameters on pendulum end trajectories:

**Amplitude change**

# Pendulum Parameter Effects:

Frequency change

# Pendulum Parameter Effects:

**Phase Difference change**

# Pendulum Parameter Effects:

**Damping Time change**

Coming back to the **second pendulum**, (point C) we can write the oscillation equations:

Initial amplitude

Damping coefficient

Damping factor

Time

Frequency

Phase difference between the second and the first pendulum

Phase difference between x and y

Overall Amplitude

$$x_2 = A_2 \cdot \exp\left(\frac{-t}{t_{damping}}\right) \cdot \sin(2 \cdot \pi \cdot f_2 \cdot t + \varphi_2)$$

$$y_2 = A_2 \cdot \exp\left(\frac{-t}{t_{damping}}\right) \cdot \sin(2 \cdot \pi \cdot f_2 \cdot t + \varphi_2 + \Delta\varphi_2)$$

- The overall amplitude is not constant but will decrease exponentially in time
- The initial amplitude, damping coefficient, frequency, phase and phase difference are all adjustable
- A phase difference of  $0^\circ$  will result in a straight line oscillation, a  $90^\circ$  in a circle and in an ellipse for any angle in between

For the **third pendulum** (the table) we can write the oscillation equations:

$$x_3 = A_3 \cdot \exp\left(\frac{-t}{t_{damping}}\right) \cdot \sin(2 \cdot \pi \cdot f_3 \cdot t + \varphi_3)$$

$$y_3 = A_3 \cdot \exp\left(\frac{-t}{t_{damping}}\right) \cdot \sin(2 \cdot \pi \cdot f_3 \cdot t + \varphi_3 + \Delta\varphi_3)$$

Initial amplitude:  $A_3$   
 Damping coefficient:  $t_{damping}$   
 Damping factor:  $\exp\left(\frac{-t}{t_{damping}}\right)$   
 Time:  $t$   
 Frequency:  $f_3$   
 Phase difference between the third and the first pendulum:  $\varphi_3$   
 Phase difference between x and y:  $\Delta\varphi_3$   
 Overall Amplitude:  $A_3$

- The overall amplitude is not constant but will decrease exponentially in time
- The initial amplitude, damping coefficient, frequency, phase and phase difference are all adjustable
- A phase difference of  $0^\circ$  will result in a straight line oscillation, a  $90^\circ$  in a circle and in an ellipse for any angle in between
